

CasaClaro

CasaClaro is a static Colombia real estate marketplace and relocation site. The repo shows a browser-only demo for comparing cities, evaluating property context, and routing buyer, seller, and partner inquiries.

Who it's for

Primary persona: a cross-border buyer or long-stay relocater who wants market, lifestyle, healthcare, repair, and visa context before choosing where to buy or move in Colombia.

- Investors
- Expatriates
- Retirees
- Sellers
- Agents / Brokers

What it does

- Lets users explore and filter Colombian cities by walkability, retiree fit, coastal living, healthcare depth, maintenance burden, and yield context.
- Builds dynamic city guide pages from one shared dataset, including neighborhood, repair, relocation, and destination detail.
- Provides a browser-based cost simulator for pricing, closing costs, renovation reserve, rent, and financed cash flow.
- Shows relocation and residency guidance with healthcare notes, visa cards, and an eligibility self-check.
- Covers rentals at both city and neighborhood level instead of only purchase scenarios.
- Captures seller, investor, partner, and data-feedback submissions with local demo persistence and optional CRM hooks.

Repo gaps called out

Backend, auth, and database: Not found in repo. Current behavior is static frontend plus browser storage, with placeholder HTTPS endpoints in JSON for future routing.

Evidence used

Summary derived from `README.md`, page entry files, `script.js`, `data/cities.json`, and `data/cities-data.js`. No behavior beyond those files is assumed.

How it works

- Frontend**Multi-page static site: HTML entry pages plus shared `styles.css` and `script.js`.
- Data layer**`script.js` fetches `data/cities.json`; pages can fall back to embedded `data/cities-data.js`.
- Client services**The app reads language and FX cache from `localStorage`, calls the Frankfurter USD/COP endpoint, and falls back to dataset values if needed.
- Rendering flow**`DOMContentLoaded -> CasaClaroApp.init()` loads data, then renders explorer, simulator, map, rentals, relocation, and city-detail modules from the shared dataset.
- Interaction**Leaflet renders the map; forms collect payloads/files in-browser, store demo submissions locally, and optionally POST to `siteMeta.integrations.routes`.

How to run

1. From repo root, start a local HTTP server: `python -m http.server 8080`
2. Open `http://localhost:8080/index.html`
3. Serve over HTTP, not `file://`, because the app fetches `data/cities.json`

Install/build/test commands: Not found in repo.

Snapshot

Repo date in data: `2026-03-29`
Rendering target: single-page PDF generated from this print layout.
